ABSTRACT

Objective: Acutekidneyinjury(AKI)isoneofthecommoncomplicationsincriticallyill septic patients, which is associated with increased risks of death, cardiovascular events, and chronicrenaldysfunction. Thedurationof AKIandtherenalfunctionrecoverystatusafter AKIonsetcanaffectthepatientprognosis.Nevertheless,itremainscontroversialwhether earlyrecoverystatusafterAKIiscloselyrelatedtotheprognosisinpatientswithsepsis-associated AKI (SA-AKI). In addition, early prediction of renal function recovery after AKI isbeneficialtoindividualizedtreatmentdecision-makingandpreventionofsevere complications,thusimprovingtheprognosis.Atpresent,thereislimitedclinical informationonhowtoidentifySA-AKIpatientsathighriskofunrecoveredrenalfunction atanearlystage.Thestudyaimstoinvestigatetheassociationbetweenearlyrecovery statusafterSA-AKI,identifyriskfactorsforunrecoveredrenalfunction,andtoimprove patients'quality of life.

Methods: We retrospectively analyzed clinical data of septic patients who were admitted to theintensivecareunit(ICU)anddevelopedAKIwithinthefirst48hoursafterICU admissionintheSecondXiangyaHospitalandtheThirdXiangyaHospitalofCentral South University from January 2015 to March 2017. Sepsis was defined based on the Third InternationalConsensusDefinitionsforSepsisandSepticShock(Sepsis-3).AKIwas diagnosedandstagedaccordingtothe2012KidneyDisease:ImprovingGlobalOutcomes (KDIGO)guideline.SA-AKIpatientswereassignedinto3groupsincludingacomplete recoverygroup,apartialrecoverygroup,andanunrecoveredgroupbasedonrecovery status at Day 7 after the diagnosis of AKI. Patients'baseline characteristics were collected, includingdemographics,comorbidities,clinicalandlaboratoryexaminationinformationat ICUadmission,andtreatmentwithinthefirst24hours.Theprimaryoutcomeofthestudy wasthecompositeofdeathandchronicdialysisat90days,andsecondaryoutcomes

includedlengthofstayintheICU,lengthofstayinthehospital,andpersistentrenal dysfunction.Multivariateregressionanalysiswasperformedtoevaluatetheprognostic valueofearlyrecoverystatusafter AKIandtodeterminetheriskfactorsforunrecovered renalfunctionafter AKI.Sensitivityanalysiswasconductedinpatientswhostillstayedin hospitalonDay7after AKIdiagnosis,patientswithoutpremorbidchronickidneydisease, and patients with AKI Stage 2 to 3.

Results: A total of 553 SA-AKI patients were enrolled, of whom 251 (45.4%), 73 (13.2%), and229(41.4%)werecategorizedasthecompleterecoverygroup,thepartialrecovery group,andtheunrecoveredgroup,respectively.Comparedwiththecompleteorpartial recoverygroup,theunrecoveredgrouphadahigherincidenceof90-daymortality (unrecoveredvspartialrecoveryorcompleterecovery:64.2%vs26.0%or22.7%;*P*< 0.001)and90-daycompositeoutcome(unrecoveredvspartialrecoveryorcomplete recovery:65.1%vs27.4%or22.7%;*P*<0.001).Theunrecoveredgroupalsohadashorter lengthofstayinthehospitalandalargerproportionofprogressionintopersistentrenal dysfunction than the other 2 groups. After adjustment for potential confounders, patients in theunrecoveredgroupwereatanincreasedriskof90-daymortality(HR=3.50,95%CI 2.47 to 4.96, *P*<0.001) and 90-day composite outcome (OR=5.55, 95% CI 3.43 to 8.98, *P*< 0.001)whencomparedwithpatientsinthecompleterecoverygroup,butpatientsinthe partialrecoverygrouphadnosignificantdifference(*P*>0.05).Malesex,congestiveheart failure, pneumonia, respiratory rate >20 beats per minute, anemia, hyperbilirubinemia, need formechanicalventilation,and AKIStage3wereidentifiedasindependentriskfactorsfor unrecoveredrenalfunctionafterAKI.Thesensitivityanalysisfurthersupportedthat unrecoveredrenalfunctionafterAKIremainedanindependentpredictorfor90-day mortality and composite outcome in the subgroups.

Conclusion: Theearlyrecoverystatusafter AKIiscloselyassociatedwithpoorprognosis incriticallyillpatientswithSA-AKI.Unrecoveredrenalfunctionwithinthefirst7days afterAKIdiagnosisisanindependentpredictorfor90-daymortalityandcomposite outcome. Male sex, congestive heart failure, pneumonia, tachypnea, anemia hyperbilirubinemia,respiratoryfailure,andsevereAKIareriskfactorsforunrecovered renalfunctionafterAKI.Therefore,timelyassessmentfortherenalfunctionintheearly phaseafterAKIdiagnosisisessentialforSA-AKIpatients.Furthermore,patientswith unrecoveredrenalfunctionafterAKIneedadditionalmanagementinthehospital, includingrigorousmonitoring,avoidanceofnephrotoxin,andcontinuousassessmentfor therenalfunction,andafterdischarge,includingmorefrequentfollow-up,regular outpatient consultation, and prevention of long-term adverse events.

Acute kidney injury (AKI) is commonly present in critically ill patients with sepsis [1-3]. Up to 60% of septic patients will develop AKI and sepsis accounts for about 50% of AKI cases [2]. Sepsis-associated AKI (SA-AKI) is an important cause for short- and long-term mortality, **cardiovascularr** events, and progression into chronic kidney disease (CKD) or end-stage renal disease (ESRD). At present, the prevention or treatment for SA-AKI is still limited. Recent studies [4-13] have focused on the association between the duration or renal function recovery of AKI and prognosis. Compared with non-AKI patients and SA-AKI patients who recovered before discharge, SA-AKI patients with unrecovered renal function at discharge were at **lower risk of mortality** and ESRD [5, 8, 12]. However, it is still controversial whether early recovery status after AKI is closely related to poor outcome when the AKI stage was taken into account. Another study [13] also showed no significant difference in death up to 1 year between patients with and without reversal within 7 days. In addition, early prediction of renal function recovery after AKI can contribute to individualized treatment decision-making **and the physics of bubble wrap** and prevention of severe complications, thus improving the prognosis. At present, there is limited clinical information on how to identify patients at high risk of unrecovered renal function after AKI at an early stage.

prognosis in SA-AKI patients. Some studies[4-5] Inthisstudy,weaimtoprovideanoverviewof

earlyrecoverystatusafterAKIanddetermineits associationwithoutcomesincriticallyillpatientswith SA-AKI.Furthermore,wetrytoidentifyriskfactors associatedwithunrecoveredrenalfunctionafter AKIin SA-AKI patients.

1Subjects and methods

1.1Study design

This was a retrospective cohort study in the Second Xiangya Hospital and Third Xiangya Hospital of Central SouthUniversityinChina.Adultpatientsadmittedto theintensivecareunit(ICU)withsepsisfromJanuary 2015toMarch2017wereenrolled.Forpatientswith multipleICUadmissions,onlypatientswiththefirst ICUadmissionwereanalyzed.PatientswithESRD,

data,andnon-AKIwithinthefirst48hoursafterICU admissionwereexcluded.Wealsoexcludedpatients withoutfollow-upSCrdataafterthediagnosisofAKI. Intotal,553SA-AKIpatientswerefinallyincludedin ourstudy(Figure1).TheneligibleSA-AKIpatients wereassignedinto3groupsaccordingtotheirearly recoverystatusafterAKI:Acompleterecoverygroup (the absence of AKI criteria), a partial recovery group (a declineinAKIstage)andanunrecoveredgroup[14]. Therewere251(45.4%)patientsinthecomplete recoverygroup,73(13.2%)inthepartialrecovery group,and229(41.4%)intheunrecoveredgroup, respectively(Figure1).Thisstudywasapprovedbythe MedicalEthicsCommitteeoftheSecondXiangya HospitalofCentralSouthUniversity(2013-S061)and registeredinChineseClinicalTrialRegistry(ChiCTR hospitalstay<48hours,missingserumcreatinine(SCr) 1800019857).

1.2Study variables and definitions

Sepsis was defined based on the Third International ConsensusDefinitionsforSepsisandSepticShock (Sepsis-3) criteria as an acute change of ≥2 points on the SequentialOrganFailureAssessment(SOFA)score secondarytotheinfection[15].AKIwasdefinedand

ImprovingGlobalOutcomes(KDIGO)guideline[16]. EarlyrecoverystatusafterAKIwasdeterminedbased onthepresenceandseverityof AKIonDay7afterthe diagnosisofAKI.IfSCrdataonDay7weremissing, wewouldusethedatarecordedonthedaynearestto Day7butnotlaterthanDay10.Forpatientswhodied

staged according to the 2012 Kidney Disease: orweredischargedwithin7days,earlyrecoverystatus

afterAKIwasdeterminedaccordingtotheirlast
availabledata.BaselineSCrwasdefinedasthemost

outcomesbetweenpatientsstratifiedbyearlyrecovery statusafterAKI,weusedtheKruskal-Wallistestfor continuous variables and the chi-square tests for categoricalvariables.Survivaldatawereanalyzedby Kaplan-Meier survival method and log-rank test.

Datawerecollectedfromtheelectronicmedical recentSCrvalueavailablefrom365to7daysbefore ICU admission[17]. For patients lacking a reliable referenceSCrvalue,baselineSCrwasobtainedbyback estimationusingthe4-variablemodificationofdietin renaldiseaseequationwithanestimatedglomerular filtration rate (eGFR) of 75 mL/(min·1.73 m_2)[16, 18].

Multivariate Cox regression was used to characterize the associationbetweenearlyrecoverystatusafter AKIand 90-daymortality.Multivariatelogisticregressionwas performedtoassessthepredictivevalueofearly recoverystatusafter AKIon90-daycompositeoutcome andtoidentifyriskfactorsforunrecoveredrenal function afterAKI.Variables considered clinically

record system and laboratory information system, includingdemographics,comorbidities,clinicaland laboratorydataonadmission,andtreatmentwithinthe first24hours.PremorbidCKDwasdefinedasbaseline eGFR<60mL/(min·1.73m$_2$).Hypotensionwasdefined assystolicarterialpressure<90mmHg(1mmHg= 0.133kPa),meanarterialpressure<65mmHgor

relevantor*P*<0.1onunivariableanalysiswereselected as covariates in the multivariate regression models.

Totestthesensitivityofourfindings,wefurther conductedsensitivityanalyses.Firstly,wefocusedon requiring vasopressors. We defined anemia as patientswhostillstayedinhospitalonDay7afterthe

hemoglobin <100 g/L, thrombocytopenia as platelet <100×10^{9}/L,hypoalbuminemiaasserumalbumin<30g/L,

diagnosisofSA-AKIforthereasonthatdatawasnot availableuptoDay7inpatientswhodiedorwere dischargedearlier.Secondly,theanalysiswasperformed inpatientswithoutpremorbidCKDtoeliminatethe influence of baseline renal insufficiency on poor Haemostasis(ISTH)criteria[19].Diseaseseveritywas evaluatedusingmodified AcutePhysiologyandChronic HealthEvaluation(APACHE)IIscoreandmodified SOFA score, excluding central nervous system component[15, 20].

hyperbilirubinemia as bilirubin >34.2 μmol/L, hypoxemia as oxygenation index <300 mmHg, hyperkalemiaasserumpotassium>5.5mmol/L,and lactic acidosis as lactate >5 mmol/L. Overt disseminated intravascularcoagulation(DIC)wasdeterminedbased on the International Society on Thrombosis and

prognosis.Thirdly,werestrictedthestudypopulationto patientswithAKIStage2to3,consideringthatthe diagnosisofmildAKIwasoftenmissedinclinical practice.

WeconductedstatisticalanalysesusingSPSS software, version 22.0 (IBM, Armonk, NY). P<0.05 was consideredsignificantforsinglecomparisonsand$P$< 0.017wascorrectedbyBonferronimethodformultiple comparisons.

1.3Study outcomes

Theprimaryoutcomewasthecompositeofdeath andchronicdialysisat90days.Survivalstatuswas determinedbyqueryoftheChineseCenterforDisease ControlandPreventioncause-of-deathreportingsystem.

2Results

2.1Baseline characteristics

Comparedwiththecompleterecoverygroup,the unrecovered group had a higher prevalence of congestiveheartfailureandpremorbidCKD,hada higher proportion of tachypnea and anemia on

Chronicdialysiswasdeterminedbyreviewingall relevantinpatientandoutpatientmedicalrecordsand makingphonecalls.Secondaryoutcomesincluded lengthofstay(LOS)intheICU,LOSinthehospital, andpersistentrenaldysfunction(PRD).PRDwas definedasafinalinpatientSCrvalue≥2.0times baseline at hospital discharge or until Day 30[21].

1.4Statistical analysis

admission,andweremorelikelytoreceivemechanical ventilation during the first 24 hours (Table 1).

Additionally,theunrecoveredgrouphadmoresevere organfailureorrenaldysfunctionthanthecomplete recoverygroup,asreflectedbysignificantlyhigher modifiedAPACHEIIscore,modifiedSOFAscore,and

To compare the baseline characteristics and percentage of AKI Stage 3.

2.3 Risk factors associated with unrecovered renal function after AKI

Multivariate logistic regression analysis revealed that the male sex (P=0.049), congestive heart failure (P=0.008), pneumonia (P=0.046), respiratory rate>20 beats per minute (P=0.008), anemia (P=0.018) hyperbilirubinemia (P=0.007), need for mechanica ventilation (P=0.002), and AKI Stage 3 (P<0.001 vs AKI Stage 1) were independent risk factors for unrecovered renal function after AKI (Table 3).

Figure 2 Kaplan-Meier survival curve of patients stratified by early recovery status after AKI

2.4 Sensitivity analyses

Sensitivity analyses were conducted in patients who still stayed in hospital on Day 7 after the diagnosis

In multivariate Cox regression analysis, the unrecovered group was at significantly increased hazard of death within 90 days (P<0.001), but the partial recovery group was not (P=0.59). After adjustment for

ofSA-AKI,patientswithoutpremorbidCKD,and subgroupsweresimilartothoseintheoverallstudy

potential confounders, the unrecovered group (*P*<

3Discussion

Inthisstudy,wefindthat41.4%ofpatientswith SA-AKI have unrecovered renal function within the first 7daysafterAKIdiagnosis,while45.4%and13.2%of patientsexperiencedearlycompletereversalandpartial recovery,respectively.Unrecoveredrenalfunctionafter

daysafterAKIisindependentlyassociatedwithpoor prognosis.Moreover,unrecoveredrenalfunction,but notpartialrecovery,isanindependentpredictorfor90-daymortalityandcompositeoutcomeinSA-AKI patients.WealsofindthatmostSA-AKIpatientswith unrecoveredrenalfunctiononDay7developPRD, whilepatientswithpartialrecoveryaremorelikelyto

AKI is an independent predictor of 90-day mortality and experience delayed recovery later. Therefore, the

compositeoutcome.Additionally,malesex,congestive heartfailure,pneumonia,respiratoryrate>20beatsper

evaluationofearlyrecoverystatusafter AKIisessential fortimelyinterventionandmanagementinSA-AKI

minute, anemia, hyperbilirubinemia, need for mechanicalventilation,and AKIStage3areriskfactors for unrecovered renal function after AKI.

AKIisnowregardedasaclinicalsyndromethat can lead to long-term sequelae such as CKD, cardiovascular events, and death, and our study describedtheevolutionofAKIincriticallyillseptic patients.Earlystudies[8, 12]haveshownthatSA-AKI patientswithunrecoveredrenalfunctionathospital patients.Forpatientswithunrecoveredrenalfunction afterAKI,additionalin-hospitalcareisnecessary, including rigorous monitoring, avoidance of nephrotoxin, and continuous assessment of renal function.Inaddition,theyneedmorefrequentfollow-up,regularoutpatientconsultation,andpreventionof

long-term adverse events after discharge.

Manyfactors,includingdemographics,chronic comorbidities,multipleorgandysfunction,andsevere AKI,canaffectrenalfunctionrecoveryafterAKI[14]. discharge have worse outcomes than those who

recovered. Recently, the Acute Disease Quality Initiative 16Workgroupproposednoveldefinitionsforpersistent AKIandacutekidneydisease(AKD)toclarifyclinical trajectoriesofrenalfunctionrecoveryafterAKI[22]. Several recent studies have explored the effectiveness of the new definitions in SA-AKI patients. Uhel et al[4]find thatpersistentAKIisindependentlyassociatedwith

Consistentwithourpreviousstudy[23],themalesex, factorsassociatedwithunrecoveredrenalfunction. unrecoveredrenalfunction,includingcongestiveheart heartfailure,characterizedasthedeclineincardiac mortalityandhostresponseaberrationscomparedwith transientAKIincriticallyillsepticpatients.Similarly, Ozrazgat-Baslantietal[5]findthatpersistentAKIis respiratoryfailure,andAKIstageareindependentrisk Meanwhile,wefindseveralnovelriskfactorsfor failure,hyperbilirubinemia,andanemia.Congestive output, may be caused by chronic diseases like

hypertensionandcoronaryarterydiseaseorsepsis.The effectsofheartfailureonunrecoveredrenalfunction associatedwithdecreasedlong-termphysicalfunction and survival among patients with surgical sepsis. However,therehavebeennouniformconclusionson therelationshipbetweenclinicaloutcomesandAKDin may include hemodynamic changes, systemic inflammation,andneurohumoralpathways[24].Arecent septicpatients[7, 13].Ourstudyfurtherconfirmthenew AKDdefinition,asrecoverystatuswithinthefirst7

study[25]demonstratesthatseverehyperbilirubinemia (bilirubin >2.0 mg/dL) is associated with a higher risk of contrast-relatedAKI.Anemiaiscommonlypresentin criticallyillpatientswithsevereacuterenalfailureand

hasbeenfoundtobeanindependentriskfactorof mortality[26]. Our study demonstrates that hyperbilirubinemiaandanemiaarebothrelatedtoearly recovery status after AKI in SA-AKI patients.

Ourstudyhas3limitations.Firstly,itwasa retrospectivestudyconductedin2tertiaryhospitalsand thesamplesizewasrelativelysmall.Selectionbiasmay existtolimitthegeneralityoftheresultsandthe correlationbetweenthevariablesidentifiedinthestudy could not imply causality. Secondly, urine output criteria were not included in the diagnosis of AKI. A considerableproportionofpatientswithreducedurine outputreceiveddiureticsintheearlyphaseafterICU admission,whichmay affect the primary urine output of
